

Replit Agent Brief: Step 1 — Segmented Tab Architecture

Context for Replit Agent:

The codebase has just undergone a moderate cleanup. The next critical step is to implement a true segmented tab architecture for the three main modules: Text Prompts, Photography, and Video.

Currently, the Photography and Video modules attempt to open in modals, which is broken and confusing. The user wants each tab to act as a full-screen mode switch, owning the entire workspace below the topbar.

Your Task:

Restructure the HTML and JS to implement this segmented architecture. Do not use modals for the core modules.

1. HTML Restructure: Three Isolated Panels

Inside the main workspace area (`.pmgv3-body` or equivalent), create three distinct container div s:

- `#pmgv3-panel-text`
- `#pmgv3-panel-photo`
- `#pmgv3-panel-video`

Move the existing content into these containers:

- **Text Panel:** Move the current two-column layout (Goal input, Tuning, Generate button on the left; Output box, Strength score, Run With AI on the right) into `#pmgv3-panel-text`.
- **Photo Panel:** Extract the Photography suite content from its current modal/hidden state. Place the brief builder (Style, Lens, Lighting, Composition, Palette pills) in the left column. Place the DALL · E image generator output area in the right column.
- **Video Panel:** Place the storyboard/scene builder tools in the left column. Place the generated video prompt/storyboard output in the right column. (Use placeholders if not fully built).

2. JS Tab Controller: State Management

Update `pmg-chassis-v3.js` (or the relevant controller) to handle the tab click events.

- The logic must toggle a visible/hidden class (or `display: none`) on the three panel containers based on the selected tab.

- Ensure the active tab state is visually reflected in the tab bar (`.pmgv3-tab.is-active`).
- The app should default to the Text Prompts tab on load.
- Remove any legacy code that attempts to open the Photography or Video modules in a modal (`openVisualStudio` , etc.).

3. CSS Layout: Consistent Two-Column Grid

- Ensure the two-column grid layout (`grid-template-columns: 1fr 1fr; gap: 16px;`) applies correctly to all three panels on desktop.
- Ensure the panels stack correctly on mobile (`max-width: 768px`).
- Verify that no aggressive `body > *` hiding rules are interfering with the new panel structure.

Goal: A clean, predictable workspace where clicking a tab completely swaps the content below it, presenting a consistent side-by-side layout for all three modes.
